

1.

$\text{push}(x) = O(\log n)$

$\text{top}() = O(1)$

$\text{pop}() = O(1)$

$\text{buildHeap}(\text{vector}<\text{int}>\{1\dots N\}) = O(n)$

2.

Any application which could normally be done with queues; however, sometimes they need a new element to jump the line. For example Oss. Programs have to wait their turn for CPU time or other limited resources. If you have a program (take a game for example) that needs the resource no matter when it is called, using a priority queue allows the game to jump the line and get the needed resources.

3.

Parent: located at  $i/2$  index.

Children:

Right Child: located at  $2*i+1$  index

Left Child: located at  $2*i$  index

4.

6,11,10,15,12,14

7.

Bubble:  $O(n^2)$  Yes

Insert:  $O(n^2)$  Yes

Merge:  $O(n \log(n))$  Yes

Radix:  $O(nk)$  Yes

Quick:  $O(n \log(n))$  No

8.

Merge sort splits in half always, merge sort can split into any ratio. Quick sort requires more memory and is very consistent with any amount of data  $O(n * \log(n))$ . Quick sort requires less memory, but does not scale well with larger data sets  $O(n^2)$ .
